About the Data

This dataset is from the world bank group where it contains multiple different variables from countries in ASEA, specifically Thailand, Malaysia, Indonesia, Singapore, Philippines, and Vietnam. It contains many variables for many topics, such as social, economic, environment, and institutions. Though there are many null values within the dataset, I've cleaned it and filtered the original dataset for the analysis of the SDG that I have chosen, which is Good Health and Well-Being.

The dataset now contains variables such as birth rate, fertility rate, child mortality, life expectancy, health expenditure, school enrollment, and urban population.

Life Expectancy Over Time - ASEAN (2000 - 2020)

This line charts tracks the life expectancy of ASEAN countries over a 20-year period.

This line charts tracks the life expectancy of ASEAN countries over a 20-year period.

Singapore maintains the highest life expectancy in the region and steadily rises.

Indonesia showed a noticeable dip around 2004 before recovering and maintaining a steady rise until it dipped at again at around 2020 during the COVID Pandemic.

Most countries showed a steady increase in life expectancy over the two decades.

Child Mortality Over Time - ASEAN (2000-2020)

This line graph shows the changes in child mortality rates across the six ASEAN Countries over a 20-year period.

Indonesia started with the highest mortality rate but had a significant and steady decline except for the spike at around 2004, achieving lower rates than the Philippines by 2020.

Singapore maintains the lowest child mortality rates in the group consistently, having a little decline in mortality rate due to it already having a low mortality rate.

There is a downward trend that is present for all countries, indicating that child mortality is decreasing across all countries

Child Mortality Vs Life Expectancy

This is a scatter plot that examines the correlation between child mortality (x-axis) and life expectancy (y-axis) with a regression line showing the downward-sloping trend line.

Demonstrates that there is a strong negative correlation between the two variables, meaning as child mortality decreases, life expectancy tends to increase.

Looking at the data points, it points that countries with better healthcare for their children also see their populations living longer overall.

Key Insight

The six ASEAN countries showed a universal decrease in child mortality and increase in life expectancy with Singapore leading the group in both fields.

It showed that countries with good healthcare and overall well-being reduces child mortality and life expectancy of the population.
